EVIDENCE LAYER	WHAT THE RESULTS SHOW	SCOPE OF INTERPRETATION
01 **Animal discovery**	549 shared differentially expressed genes and 154 shared pathways; matrix and smooth-muscle programmes in uraemic calcification and dissection-or-aneurysm models.	478 shared genes changed concordantly; 71 changed in opposite directions. Animal overlap is not dissection-specific.
02 **Human arterial tissue**	Ossification passed correction in all three datasets. Matrix organization passed in two; smooth-muscle findings varied by dataset.	GSE38750 confounds disease with arterial site. GSE38751 is a small same-study, same-site comparison, not independent replication.
03 **Genetic analyses**	No primary MR estimate passed BH correction. Genetic correlation was not estimable; colocalization was prior-sensitive and reverse MR was instrument-limited.	Smaller effects and shared genetic architecture remain unresolved. The fitted regional model limits the colocalization inference.
04 **Immune & classifier checks**	No immune programme passed correction in either human immune-analysis dataset. Random-gene controls matched internal classification; external performance varied.	Programme scores are not cell fractions. Retrospective tissue classification does not test future disease risk.

INTERPRETATION	**Shared arterial-remodelling expression programmes across experimental models, with narrower, context-dependent human support strongest for ossification-related expression.**

A focused basis for mechanistic studies; no causal mechanism, therapeutic target or treatment effect is established.
